#### INTRODUCTION

Introduce existing algorithms for integration problems.

show drwabacks

1. Non-adaptive 2. adaptive no guarantees 3. maybe more

introduce

$$INT(f) = \int_{a}^{b} f(x)dx \in \mathbb{R}.$$
 (1.1)

#### PROBLEM STATEMENT AND ASSUMPTIONS

In the previous chapter, I introduced the univariate integration problem,  $INT(f) = \int_a^b f(x)dx \in \mathbb{R}$ . (how to make the equality stay in one line.) In order to build adaptive, automatic algorithms with guarantees to solve the problem, we firstly consider two straight-forward yet widely used fixed cost algorithms, trapezoidal rule and Simpson's rule.

The composite trapezoidal rule can be defined as:

$$T(f,n) = \frac{b-a}{2n} \sum_{j=0}^{n} (f(u_j) + f(u_{j+1})), \tag{2.1}$$

where

$$u_j = a + \frac{j(b-a)}{n}, \quad j = 0, \dots, n, \quad n \in \mathbb{N}.$$
 (2.2)

It uses n+1 function values where those n+1 node points are equally spaced between [a, b]. In the meanwhile, the composite Simpson's rule can be defined as:

$$S(f,n) = \frac{b-a}{12n} \sum_{j=0}^{6n-2} (f(v_j) + 4f(v_{j+1}) + f(v_{j+2})), \tag{2.3}$$

(double check index and fraction.) where

$$v_j = a + \frac{j(b-a)}{n}, \qquad j = 0, \dots, 6n, \qquad n \in \mathbb{N}.$$
 (2.4)

It uses 6n + 1 equally spaced function values, which form 6n intervals/subintervals between [a.b]. The reason why we use 6n intervals is that firstly, Simpson's rule requires an even number of intervals. Secondly, we are going to use the third order finite difference method to approximate the third derivative of f in later chapters. The third order finite difference method requires the number of intervals to be a multiple of 3. All in all, the number of intervals for input data has to be a multiple of 6.

Finding a proper way to approximate the first and third order derivatives plays an important role in constructing our algorithms, especially in finding the upper bound of approximation error. If we look back at the traditional non-adaptive trapezoidal rule and Simpson's rule, the upper bound of approximation error can be represented in terms of the total variation of a particular derivative of integrand.

$$\operatorname{err}(f, n) \le \overline{\operatorname{err}}(f, n) := C(n) \operatorname{Var}(f^{(p)}).$$
 (2.5)

For trapezoidal rule,  $C(n)=(b-a)^2/8n^2, p=1$  (ref). For Simpson's rule,  $C(n)=(b-a)^4/5832n^4, p=3$  (ref).

To better define the total variation, Var(f), firstly we introduce  $\widehat{V}(f, \{x_i\}_{i=0}^{n+1})$  as an approximation to the total variation:

$$\widehat{V}(f, \{x_i\}_{i=0}^{n+1}) = \sum_{i=1}^{n-1} |f(x_{i+1}) - f(x_i)|, \tag{2.6}$$

where  $\{x_i\}_{i=0}^{n+1}$  is any given partition with no necessity of equal spacing, and  $a = x_0 \le x_1 < \cdots < x_n \le x_{n+1} = b$ . (1. explain two side points. 2. how to make the inequality stay in one line.)

From the definition of  $\widehat{V}(f, \{x_i\}_{i=0}^{n+1})$ , the total variation can be defined as an upper of bound of  $\widehat{V}(f, \{x_i\}_{i=0}^{n+1})$ :

$$\operatorname{Var}(f) := \sup_{n \in \mathbb{N}, \{x_i\}_{i=0}^{n+1}} \left\{ \widehat{V}(f, \{x_i\}_{i=0}^{n+1}) \right\}, \tag{2.7}$$

For an algorithm with finite error bound, it is trivial that the input functions must be in a space of integrands such that it is continuous in [a, b] with finite total variations of derivatives, to the proper order, of the functions:

$$\mathcal{V}^p[a,b] := \{ f \in C[a,b] : Var(f^{(p)}) < \infty \}. \tag{2.8}$$

For trapezoidal rule, p = 1. For Simpson's rule, p = 3.

In order to build an adaptive automatic and guaranteed algorithm, we have to set up the following pre-existing condition that all functions to be approximated must lie in a cone space of integrands for which  $\widehat{V}(f, \{x_i\}_{i=0}^{n+1})$  does not underestimate  $\operatorname{Var}(f)$  too much:

$$C^{p} := \left\{ f \in \mathcal{V}^{p}, \operatorname{Var}(f^{(p)}) \leq \mathfrak{C}(\operatorname{size}(\{x_{i}\}_{i=0}^{n+1})) \widehat{V}(f^{(p)}, \{x_{i}\}_{i=0}^{n+1}), \right.$$
for all choices of  $n \in \mathbb{N}$ , and  $\{x_{i}\}_{i=0}^{n+1}$  with  $\operatorname{size}(\{x_{i}\}_{i=0}^{n+1}) < \mathfrak{h} \right\}, \quad (2.9)$ 

The cone space  $C^p$  is a subspace of  $V^p[a,b]$ . Details about the cut-off value  $\mathfrak{h}$  and  $\operatorname{size}(\{x_i\}_{i=0}^{n+1})$  will be explained in the next chapter.

WIth the cone space defined, we can start constructing our trapezoidal rule algorithm and Simpson's rule algorithm for functions in  $C^p$ , with appropriate value of p. To begin with, I will show how the algorithms provide guarantees of success in Chapter 3.

#### ERROR BOUND ANALYSIS

I need to translate trap language to sim language to make them uniform. I need to explain the deduction for trap without using and assumptions or known theories in the paper. I also need to figure out notations. I need the notations not to conflict. Then I need to go to chapter 2 and change notation.

In the previous part???

**3.1 Trapezoidal Rule** From (ref), the error bound of Trapezoidal rule is related to the variation of the third derivatives of the function to be integrated:

$$\operatorname{err}(f,n) \le \overline{\operatorname{err}}(f,n) := \frac{(b-a)^2 \operatorname{Var}(f')}{8n^2}.$$
(3.1)

Note that  $\widetilde{F}_n(f)$  never overestimates  $|f|_{\widetilde{\mathcal{F}}}$  because

$$|f|_{\widetilde{\mathcal{F}}} = \|f' - A_2(f)'\|_1 = \sum_{i=1}^{n-1} \int_{x_i}^{x_{i+1}} |f'(x) - A_2(f)'(x)| dx$$

$$\geq \sum_{i=1}^{n-1} \left| \int_{x_i}^{x_{i+1}} [f'(x) - A_2(f)'(x)] dx \right| = \|A_n(f)' - A_2(f)'\|_1 = \widetilde{F}_n(f).$$

To find an upper bound on  $|f|_{\widetilde{\mathcal{F}}} - \widetilde{F}_n(f)$ , note that

$$|f|_{\widetilde{\mathcal{F}}} - \widetilde{F}_n(f) = |f|_{\widetilde{\mathcal{F}}} - |A_n(f)|_{\widetilde{\mathcal{F}}} \le |f - A_n(f)|_{\widetilde{\mathcal{F}}} = ||f' - A_n(f)'||_1,$$

since  $(f - A_n(f))(x)$  vanishes for x = 0, 1. Moreover,

$$||f' - A_n(f)'||_1 = \sum_{i=1}^{n-1} \int_{x_i}^{x_{i+1}} |f'(x) - (n-1)[f(x_{i+1}) - f(x_i)]| dx.$$
 (3.2)

Now we bound each integral in the summation. For i = 1, ..., n - 1, let  $\eta_i(x) = f'(x) - (n-1)[f(x_{i+1}) - f(x_i)]$ , and let  $p_i$  denote the probability that  $\eta_i(x)$  is non-negative:

$$p_i = (n-1) \int_{x_i}^{x_{i+1}} \mathbb{1}_{[0,\infty)}(\eta_i(x)) dx,$$

and so  $1 - p_i$  is the probability that  $\eta_i(x)$  is negative. Since  $\int_{x_i}^{x_{i+1}} \eta_i(x) dx = 0$ , we know that  $\eta_i$  must take on both non-positive and non-negative values. Invoking the Mean Value Theorem, it follows that

$$\frac{p_i}{n-1} \sup_{x_i \le x \le x_{i+1}} \eta_i(x) \ge \int_{x_i}^{x_{i+1}} \max(\eta_i(x), 0) \, \mathrm{d}x$$

$$= \int_{x_i}^{x_{i+1}} \max(-\eta_i(x), 0) \, \mathrm{d}x \le \frac{-(1-p_i)}{n-1} \inf_{x_i \le x \le x_{i+1}} \eta_i(x).$$

These bounds allow us to derive bounds on the integrals in (3.2):

$$\int_{x_{i}}^{x_{i+1}} |\eta_{i}(x)| dx 
= \int_{x_{i}}^{x_{i+1}} \max(\eta_{i}(x), 0) dx + \int_{x_{i}}^{x_{i+1}} \max(-\eta_{i}(x), 0) dx 
= 2(1 - p_{i}) \int_{x_{i}}^{x_{i+1}} \max(\eta_{i}(x), 0) dx + 2p_{i} \int_{x_{i}}^{x_{i+1}} \max(-\eta_{i}(x), 0) dx 
\leq \frac{2p_{i}(1 - p_{i})}{n - 1} \left[ \sup_{x_{i} \leq x \leq x_{i+1}} \eta_{i}(x) - \inf_{x_{i} \leq x \leq x_{i+1}} \eta_{i}(x) \right] 
\leq \frac{1}{2(n - 1)} \left[ \sup_{x_{i} \leq x \leq x_{i+1}} f'(x) - \inf_{x_{i} \leq x \leq x_{i+1}} f'(x) \right],$$

since  $p_i(1 - p_i) \le 1/4$ .

Plugging this bound into (3.2) yields

$$||f' - f(1) + f(0)||_{1} - \widetilde{F}_{n}(f) = |f|_{\widetilde{\mathcal{F}}} - \widetilde{F}_{n}(f)$$

$$\leq ||f' - A_{n}(f)'||_{1}$$

$$\leq \frac{1}{2n - 2} \sum_{i=1}^{n-1} \left[ \sup_{x_{i} \leq x \leq x_{i+1}} f'(x) - \inf_{x_{i} \leq x \leq x_{i+1}} f'(x) \right]$$

$$\leq \frac{\operatorname{Var}(f')}{2n - 2} \leq \frac{\tau}{2n - 2} |f|_{\widetilde{\mathcal{F}}},$$

So

$$|f|_{\widetilde{\mathcal{F}}} \le \frac{2n-2}{2n-2-\tau}\widetilde{F}_n(f).$$

Then we will have

$$\overline{\text{err}}(f,n) := \frac{(b-a)^2 \operatorname{Var}(f')}{8n^2} \le \frac{(b-a)\tau}{4(n-1)(2n-2-\tau)} \widetilde{F}_n(f).$$

#### 3.2 Simpson's Rule

From (2.5) in Chapter 2, we know that the error bound of approximations using Simpson's rule can be bounded by the variation of the third derivatives of the function. We do not have the variation of the third derivatives of the function. In order to find the error bound, we introduced the cone space of input functions so that the approximation error of functions within the space can be bounded by  $\hat{V}(f''', \{x_i\}_{i=0}^{n+1})$ . However, we cannot use  $\hat{V}(f''', \{x_i\}_{i=0}^{n+1})$  to approximate Var(f''') because it depends on values of f''', not values of f. In this case, we consider the following approximation to Var(f''') which is closely related to  $\hat{V}(f''', \{x_i\}_{i=0}^{n+1})$ :

$$\widetilde{V}_n(f) = \frac{27n^3}{(b-a)^3} \sum_{j=1}^{n-1} |f(v_{3j+3}) - 3f(v_{3j+2}) + 3f(v_{3j+1}) - 2f(v_{3j}) + 3f(v_{3j-1}) - 3f(v_{3j-2}) + f(v_{3j-3})|, \quad (3.3)$$

We use divided differences to explain The relationship between (2.6) and (3.3). Let  $h = v_{j+1} - v_j = (b-a)/3n$  and

$$f[v_j] = f(v_j), \text{ for } j = 0, \dots, 3n,$$
 
$$f[v_j, v_{j-1}] = \frac{f(v_j) - f(v_{j-1})}{h}, \text{ for } j = 1, \dots, 3n,$$
 
$$f[v_j, v_{j-1}, v_{j-2}] = \frac{f(v_j) - 2f(v_{j-1}) + f(v_{j-2})}{2h^2}, \text{ for } j = 2, \dots, 3n,$$
 
$$f[v_j, v_{j-1}, v_{j-2}, v_{j-3}] = \frac{f(v_j) - 3f(v_{j-1}) + 3f(v_{j-2}) - f(v_{j-3})}{6h^3}, \text{ for } j = 3, \dots, 3n.$$

According to Mean Value Theorem for divided differences, (ref), for all  $j = 1, 2, \dots, n$ , there exists  $x_j \in (v_{3j-3}, v_{3j})$  such that

$$f[v_{3j}, v_{3j-1}, v_{3j-2}, t_{3j-3}] = \frac{f'''(x_j)}{6},$$

for  $j=1,2,\cdots,n$ . This implies that

$$f'''(x_j) = \frac{f(v_{3j}) - 3f(v_{3j-1}) + 3f(v_{3j-2}) - f(v_{3j-3})}{h^3},$$

$$= \frac{27n^3}{(b-a)^3} [f(v_{3j}) - 3f(v_{3j-1}) + 3f(v_{3j-2}) - f(v_{3j-3})]. \quad (3.4)$$

If we combine (3.3) and (3.4) together, we obtain

$$\widetilde{V}_n(f) = \sum_{j=1}^{n-1} |f'''(x_{j+1}) - f'''(x_j)| = \widehat{V}(f''', \{x_j\}_{j=0}^{n+1}).$$
(3.5)

Then we can use  $\widetilde{V}_n(f)$  to approximate  $\operatorname{Var}(f''')$  by just using function values.

(Add the formula here.)

#### ADAPTIVE, AUTOMATIC ALGORITHMS WITH GUARANTEES

**4.1 Basic Concepts** AA I need to explain the embedded mechanism and stopping criteria with tolerance, max iteration and max number of points. In the following subsections, I need detailed explanation of the algorithms.

#### 4.2 Trapezoidal Rule

**Algorithm 1** (Adaptive Univariate Integration). Let the sequence of algorithms  $\{T_n\}_{n\in\mathcal{I}}$ ,  $\{\widetilde{F}_n\}_{n\in\mathcal{I}}$ , and  $\{F_n\}_{n\in\mathcal{I}}$  be as described above. Let  $\tau\geq 2$  be the cone constant. Set i=1. Let  $n_1=\lceil (\tau+1)/2\rceil+1$ . For any error tolerance  $\varepsilon$  and input function f, do the following:

Stage 1. Estimate  $||f' - f(1) + f(0)||_1$  and bound  $\operatorname{Var}(f')$ . Compute  $\widetilde{F}_{n_i}(f)$  in (??) and  $F_{n_i}(f)$  in (??).

Stage 2. Check the necessary condition for  $f \in \mathcal{C}_{\tau}$ . Compute

$$\tau_{\min,n_i} = \frac{F_{n_i}(f)}{\widetilde{F}_{n_i}(f) + F_{n_i}(f)/(2n_i - 2)}.$$

If  $\tau \geq \tau_{\min,n_i}$ , then go to stage 3. Otherwise, set  $\tau = 2\tau_{\min,n_i}$ . If  $n_i \geq (\tau + 1)/2$ , then go to stage 3. Otherwise, choose

$$n_{i+1} = 1 + (n_i - 1) \left\lceil \frac{\tau + 1}{2n_i - 2} \right\rceil.$$

Go to Stage 1.

Stage 3. Check for convergence. Check whether  $n_i$  is large enough to satisfy the error tolerance, i.e.

$$\widetilde{F}_{n_i}(f) \le \frac{4\varepsilon(n_i-1)(2n_i-2-\tau)}{\tau}.$$

If this is true, then return  $T_{n_i}(f)$  and terminate the algorithm. If this is not true, choose

$$n_{i+1} = 1 + (n_i - 1) \max \left\{ 2, \left\lceil \frac{1}{(n_i - 1)} \sqrt{\frac{\tau \widetilde{F}_{n_i}(f)}{8\varepsilon}} \right\rceil \right\}.$$

Go to Stage 1.

#### 4.3 Simpson's Rule

**Algorithm 2** (Adaptive Univariate Integration). Given an interval [a, b], an inflation function,  $\mathfrak{C}$ , a positive key mesh size  $\mathfrak{h}$ , a positive error tolerance,  $\varepsilon$ , and a routine for generating values of the integrand, f, set l = 1, and  $n_1 = 2(\lfloor (b-a)/\mathfrak{h} \rfloor + 1)$ .

**Stage 1** Compute the error estimate  $\widetilde{\text{err}}(f, n_l)$  according to (??).

Stage 2 If  $\widetilde{\operatorname{err}}(f, n_l) \leq \varepsilon$ , then return the Simpson's rule approximation  $S_{n_l}(f)$  as the answer.

**Stage 3** Otherwise let  $n_{l+1} = \max(2, m)\eta_l$ , where

$$m = \min\{r \in \mathbb{N} : \eta(rn_l)\widetilde{V}_{n_l(f)} \le \varepsilon\}, \text{ with } \eta(n) := \frac{(b-a)^4\mathfrak{C}(2(b-a)/n)}{5832n^4}.$$

increase l by one, and go to 1.

**Theorem 1.** Algorithm 2 is successful, i.e.,

$$\left| \int_a^b f(x) dx - \mathit{integral}(f, a, b, \varepsilon) \right| \leq \varepsilon, \qquad \forall f \in \mathcal{C}.$$

#### COMPUTATIONAL COST OF GUARANTEED ALGORITHMS

#### 5.1 Traezoidale rule

**Theorem 2.** Let  $\sigma > 0$  be some fixed parameter, and let  $\mathcal{B}_{\sigma} = \{ f \in \mathcal{V}^1 : \operatorname{Var}(f') \leq \sigma \}$ . Let  $T \in \mathcal{A}(\mathcal{B}_{\sigma}, \mathbb{R}, \operatorname{INT}, \Lambda^{\operatorname{std}})$  be the non-adaptive trapezoidal rule defined by Algorithm ??, and let  $\varepsilon > 0$  be the error tolerance. Then this algorithm succeeds for  $f \in \mathcal{B}_{\sigma}$ , i.e.,  $|\operatorname{INT}(f) - T(f, \varepsilon)| \leq \varepsilon$ , and the cost of this algorithm is  $\left\lceil \sqrt{\sigma/(8\varepsilon)} \right\rceil + 1$ , regardless of the size of  $\operatorname{Var}(f')$ .

Now let  $T \in \mathcal{A}(\mathcal{C}_{\tau}, \mathbb{R}, \mathrm{INT}, \Lambda^{\mathrm{std}})$  be the adaptive trapezoidal rule defined by Algorithm 1, and let  $\tau$ ,  $n_1$ , and  $\varepsilon$  be as described there. Let  $\mathcal{C}_{\tau}$  be the cone of functions defined in (??). Then it follows that Algorithm 1 is successful for all functions in  $\mathcal{C}_{\tau}$ , i.e.,  $|\mathrm{INT}(f) - T(f, \varepsilon)| \leq \varepsilon$ . Moreover, the cost of this algorithm is bounded below and above as follows:

$$\max\left(\left\lceil\frac{\tau+1}{2}\right\rceil, \left\lceil\sqrt{\frac{\operatorname{Var}(f')}{8\varepsilon}}\right\rceil\right) + 1$$

$$\leq \max\left(\left\lceil\frac{\tau+1}{2}\right\rceil, \left\lceil\sqrt{\frac{\tau \|f'-f(1)+f(0)\|_{1}}{8\varepsilon}}\right\rceil\right) + 1$$

$$\leq \cot(T, f; \varepsilon)$$

$$\leq \sqrt{\frac{\tau \|f'-f(1)+f(0)\|_{1}}{2\varepsilon}} + \tau + 4 \leq \sqrt{\frac{\tau \operatorname{Var}(f')}{4\varepsilon}} + \tau + 4. \quad (5.1)$$

The algorithm is computationally stable, meaning that the minimum and maximum costs for all integrands, f, with fixed  $||f' - f(1) + f(0)||_1$  or Var(f') are an  $\varepsilon$ -independent constant of each other.

#### 5.2 Simpson's rule

**Theorem 3.** Let  $N(f, \varepsilon)$  denote the final number of  $n_l$  in Stage 2 when the algorithm terminates. Then this number is bounded below and above in terms of the true, yet

unknown, Var(f''').

$$\max\left(\left\lfloor \frac{2(b-a)}{\mathfrak{h}}\right\rfloor + 1, \left\lceil (b-a)\left(\frac{\operatorname{Var}(f''')}{5832\varepsilon}\right)^{1/4}\right\rceil\right) \leq N(f,\varepsilon) \\
\leq 2\min\left\{n \in \mathbb{N} : n \geq 2\left(\left\lfloor \frac{(b-a)}{\mathfrak{h}}\right\rfloor + 1\right), \eta(n)\operatorname{Var}(f''') \leq \varepsilon\right\} \\
\leq 2\min_{0 < \alpha \leq 1}\max\left(2\left(\left\lfloor \frac{(b-a)}{\alpha\mathfrak{h}}\right\rfloor + 1\right), (b-a)\left(\frac{\mathfrak{C}(\alpha\mathfrak{h})\operatorname{Var}(f''')}{5832\varepsilon}\right)^{1/4} + 1\right). (5.2)$$

The number of function values required by the algorithm is  $3N(f,\varepsilon)+1$ .

*Proof.* No matter what inputs f and  $\varepsilon$  are provided,  $N(f, \varepsilon) \geq n_1 = 2(\lfloor (b-a)/\mathfrak{h} \rfloor + 1)$ . Then the number of intervals increases until  $\widetilde{\text{err}}(f, n) \leq \varepsilon$ , which by (??) implies that  $\overline{\text{err}}(f, n) \leq \varepsilon$ . This implies the lower bound on  $N(f, \varepsilon)$ .

Let L be the value of l for which Algorithm 2 terminates. Since  $n_1$  satisfies the upper bound, we may assume that  $L \geq 2$ . Let m be the integer found in Step 3, and let  $m^* = \max(2, m)$ . Note that  $\eta((m^* - 1)n_{L-1}) \operatorname{Var}(f''') > \varepsilon$ . For  $m^* = 2$ , this is true because  $\eta(n_{L-1}) \operatorname{Var}(f''') \geq \eta(n_{L-1}) \widetilde{V}_{n_{L-1}}(f) = \widetilde{\operatorname{err}}(f, n_{L-1}) > \varepsilon$ . For  $m^* = m > 2$  it is true because of the definition of m. Since  $\eta$  is a decreasing function, it follows that

$$(m^* - 1)n_{L-1} < n^* := \min \left\{ n \in \mathbb{N} : n \ge \left| \frac{2(b-a)}{n} \right| + 1, \eta(n) \operatorname{Var}(f''') \le \varepsilon \right\}.$$

Therefore  $n_L = m^* n_{L-1} < m^* \frac{n^*}{m^*-1} = \frac{m^*}{m^*-1} n^* \le 2n^*$ .

To prove the latter part of the upper bound, we need to prove that

$$n^* \le \max\left(\left\lfloor \frac{2(b-a)}{\alpha \mathfrak{h}} \right\rfloor + 1, (b-a) \left(\frac{\mathfrak{C}(\alpha \mathfrak{h}) \operatorname{Var}(f''')}{5832\varepsilon}\right)^{1/4} + 1\right), \quad 0 < \alpha < 1.$$

For fixed  $\alpha \in (0, 1]$ , we only need to consider that case where  $n^* > \lfloor 2(b-a)/(\alpha \mathfrak{h}) \rfloor + 1$ . This implies that  $n^* - 1 > \lfloor 2(b-a)/(\alpha \mathfrak{h}) \rfloor \ge 2(b-a)/(\alpha \mathfrak{h})$  thus  $\alpha \mathfrak{h} \ge 2(b-a)/(n^*-1)$ .

Also by the definition of  $n^*$ ,  $\eta$ , and  $\mathfrak{C}$  is non-decreasing:

$$\begin{split} &\eta(n^*-1)\operatorname{Var}(f''')>\varepsilon,\\ &\Rightarrow 1<\left(\frac{\eta(n^*-1)\operatorname{Var}(f''')}{\varepsilon}\right)^{1/4},\\ &\Rightarrow n^*-1< n^*-1\left(\frac{\eta(n^*-1)\operatorname{Var}(f''')}{\varepsilon}\right)^{1/4},\\ &= n^*-1\left(\frac{(b-a)^4\mathfrak{C}(2(b-a)/(n^*-1))\operatorname{Var}(f''')}{5832(n^*-1)^4\varepsilon}\right)^{1/4},\\ &\leq (b-a)\left(\frac{\mathfrak{C}(\alpha\mathfrak{h})\operatorname{Var}(f''')}{5832\varepsilon}\right)^{1/4}. \end{split}$$

This completes the prove of latter part of the upper bound.

#### LOWER BOUND OF COMPLEXITY

**6.1 Traezoidale rule** Next, we derive a lower bound on the cost of approximating functions in the ball  $\mathcal{B}_{\sigma}$  and in the cone  $\mathcal{C}_{\tau}$  by constructing fooling functions. Following the arguments of Section ??, we choose the triangle shaped function  $f_0: x \mapsto 1/2 - |1/2 - x|$ . Then

$$|f_0|_{\widetilde{\mathcal{F}}} = ||f_0' - f_0(1) + f_0(0)||_1 = \int_0^1 |\operatorname{sign}(1/2 - x)| \, dx = 1,$$
  
 $|f_0|_{\mathcal{F}} = \operatorname{Var}(f_0') = 2 = \tau_{\min}.$ 

For any  $n \in \mathcal{J} := \mathbb{N}_0$ , suppose that the one has the data  $L_i(f) = f(\xi_i)$ ,  $i = 1, \ldots, n$  for arbitrary  $\xi_i$ , where  $0 = \xi_0 \le \xi_1 < \cdots < \xi_n \le \xi_{n+1} = 1$ . There must be some  $j = 0, \ldots, n$  such that  $\xi_{j+1} - \xi_j \ge 1/(n+1)$ . The function  $f_1$  is defined as a triangle function on the interval  $[\xi_j, \xi_{j+1}]$ :

$$f_1(x) := \begin{cases} \frac{\xi_{j+1} - \xi_j - |\xi_{j+1} + \xi_j - 2x|}{8} & \xi_j \le x \le \xi_{j+1}, \\ 0 & \text{otherwise.} \end{cases}$$

This is a piecewise linear function whose derivative changes from 0 to 1/4 to -1/4 to 0 provided  $0 < \xi_j < \xi_{j+1} < 1$ , and so  $|f_1|_{\mathcal{F}} = \text{Var}(f_1') \le 1$ . Moreover,

INT
$$(f) = \int_0^1 f_1(x) dx = \frac{(\xi_{j+1} - \xi_j)^2}{16} \ge \frac{1}{16(n+1)^2} =: g(n),$$
$$g^{-1}(\varepsilon) = \left\lceil \sqrt{\frac{1}{16\varepsilon}} \right\rceil - 1.$$

Using these choices of  $f_0$  and  $f_1$ , along with the corresponding g above, one may invoke Theorems ??-??, and Corollary ?? to obtain the following theorem.

**Theorem 4.** For  $\sigma > 0$  let  $\mathcal{B}_{\sigma} = \{ f \in \mathcal{V}^1 : \operatorname{Var}(f') \leq \sigma \}$ . The complexity of integration on this ball is bounded below as

$$comp(\varepsilon, \mathcal{A}(\mathcal{B}_{\sigma}, \mathbb{R}, INT, \Lambda^{std}), \mathcal{B}_{s}) \geq \left\lceil \sqrt{\frac{\min(s, \sigma)}{16\varepsilon}} \right\rceil - 1.$$

(6.1a)

Algorithm?? using the trapezoidal rule has optimal order in the sense of Theorem ??.

For  $\tau > 2$ , the complexity of the integration problem over the cone of functions  $C_{\tau}$  defined in (??) is bounded below as

$$comp(\varepsilon, \mathcal{A}(\mathcal{C}_{\tau}, \mathbb{R}, INT, \Lambda^{std}), \mathcal{B}_{s}) \geq \left\lceil \sqrt{\frac{(\tau - 2)s}{32\tau\varepsilon}} \right\rceil - 1.$$

The adaptive trapezoidal Algorithm 1 has optimal order for integration of functions in  $C_{\tau}$  in the sense of Corollary ??.

#### **6.2** Simpson's rule building fooling function:

$$bump(x;t,h) := \begin{cases} (x-t)^3/6, & t \le x < t+h, \\ [-3(x-t)^3 + 12h(x-t)^2 - 12h^2(x-t) + 4h^3]/6, & t+h \le x < t+2h, \\ [3(x-t)^3 - 24h(x-t)^2 + 60h^2(x-t) - 44h^3]/6, & t+2h \le x < t+3h, \\ (t+4h-x)^3/6, & t+3h \le x < t+4h, \\ 0, & \text{otherwise,} \end{cases}$$

$$\operatorname{bump}'''(x;t,h) := \begin{cases} 1, & t \le x < t+h, \\ -3, & t+h \le x < t+2h, \\ 3, & t+2h \le x < t+3h,, \\ -1, & t+3h \le x < t+4h, \\ 0, & \text{otherwise,} \end{cases}$$
 (6.1b)

$$Var(bump'''(\cdot; t, h)) \le 16 \text{ with equality if } a < t < t + 4h < b, \tag{6.1c}$$

Var(bump'''(
$$\cdot$$
;  $t, h$ ))  $\leq 16$  with equality if  $a < t < t + 4h < b$ , (6.1c)
$$\int_{a}^{b} \operatorname{peak}(x; t, h) dx = h^{4}.$$
 (6.1d)

The following double-bump function always lies in C:

twobp
$$(x; t, h, \pm) := \text{bump}(x; a, \mathfrak{h}) \pm \frac{15[\mathfrak{C}(h) - 1]}{16} \text{bump}(x; t, h)$$
$$a + 5\mathfrak{h} \le h \le b - 5h, 0 \le h < \mathfrak{h}. \quad (6.2a)$$

$$Var(twobp'''(x;t,h,\pm)) = 15 + 16\frac{15[\mathfrak{C}(h)-1]}{16} = 15\mathfrak{C}(h).$$
 (6.2b)

From this definition it follows that

$$\mathfrak{C}(\operatorname{size}(\{x_j\}_{j=0}^{n+1}))\widehat{V}(\operatorname{twobp}'''(x;t,h,\pm),\{x_j\}_{j=0}^{n+1})$$

$$\geq \begin{cases} 15\mathfrak{C}(h) = \operatorname{Var}(\operatorname{twobp}'''(x;t,h,\pm)), h \leq \operatorname{size}(\{x_j\}_{j=0}^{n+1})) < \mathfrak{h} \\ \mathfrak{C}(0)\operatorname{Var}(\operatorname{twobp}'''(x;t,h,\pm)), 0 \leq \operatorname{size}(\{x_j\}_{j=0}^{n+1})) < h \end{cases}$$

$$\geq \operatorname{Var}(\operatorname{twobp}'''(x;t,h,\pm))$$

Although twobp"'( $x; t, h, \pm$ ) may have a bump with arbitrarily small width 4h, the height is small enough for twobp"'( $x; t, h, \pm$ ) to lie in the cone.

complexity:

**Theorem 5.** Let int be any (possibly adaptive) algorithm that succeeds for all integrands in C, and only uses function values. For any error tolerance  $\varepsilon > 0$  and any arbitrary value of Var(f'''), there will be some  $f \in C$  for which int must use at least

$$-\frac{5}{4} + \frac{b - a - 5\mathfrak{h}}{8} \left[ \frac{[\mathfrak{C}(0) - 1] \operatorname{Var}(f''')}{\varepsilon} \right]^{1/4}$$
(6.3)

function values. As  $Var(f''')/\varepsilon \to \infty$  the asymptotic rate of increase is the same as the computational cost of integral.

*Proof.* For any positive  $\alpha$ , suppose that  $\operatorname{int}(\cdot, a, b, \varepsilon)$  evaluates integrand  $\alpha$  bump<sup>"'</sup> $(\cdot; t, h)$  at n nodes before returning to an answer. Let  $\{x_j\}_{j=1}^m$  be the m < n ordered

nodes used by  $\operatorname{int}(\cdot, a, b, \varepsilon)$  that fall in the interval  $(x_0, x_{m+1})$  where  $x_0 := a + 3\mathfrak{h}$ ,  $x_{m+1} := b - h$  (why h but not  $\mathfrak{h}$  or 5h?) and  $h := (b - a - 5\mathfrak{h})/(4n + 5)$ . There must  $a_i = a_i + a_i$ 

$$\frac{x_{j+1} - x_j}{4} \ge \frac{x_{m+1} - x_0}{4(m+1)} \ge \frac{x_{m+1} - x_0}{4(n+1)} = \frac{b - a - 5\mathfrak{h} - h}{4n + 4} = h.$$

Choose one such  $x_j$  and call it t. The choice of t and h ensures that  $\operatorname{int}(\cdot, a, b, \varepsilon)$  cannot distinguish between  $\alpha \operatorname{bump}(\cdot; t, h)$  and  $\alpha \operatorname{twobp}(\cdot; t, h, \pm)$ . Thus

$$\operatorname{int}(\alpha \operatorname{twobp}(\cdot; t, h, \pm), a, b, \varepsilon) = \operatorname{int}(\alpha \operatorname{bump}(\cdot; t, h), a, b, \varepsilon)$$

Moreover,  $\alpha$ bump $(\cdot; t, h)$  and  $\alpha$ twobp $(\cdot; t, h, \pm)$  are all in the cone  $\mathcal{C}$ . This means that int is successful for all of the functions.

$$\begin{split} \varepsilon & \geq \frac{1}{2} \left[ \left| \int_a^b \alpha \mathrm{twobp}(x;t,h,-) dx - \mathrm{int}(\alpha \mathrm{twobp}(\cdot;t,h,-),a,b,\varepsilon) \right| \right. \\ & + \left| \int_a^b \alpha \mathrm{twobp}(x;t,h,+) dx - \mathrm{int}(\alpha \mathrm{twobp}(\cdot;t,h,+),a,b,\varepsilon) \right| \left. \right] \\ & \geq \frac{1}{2} \left[ \left| \mathrm{int}(\alpha \mathrm{bump}(\cdot;t,h,-),a,b,\varepsilon) - \int_a^b \alpha \mathrm{twobp}(x;t,h,-) dx \right| \right. \\ & + \left| \int_a^b \alpha \mathrm{twobp}(x;t,h,+) dx - \mathrm{int}(\alpha \mathrm{bump}(\cdot;t,h,+),a,b,\varepsilon) \right| \left. \right] \\ & \geq \frac{1}{2} \left| \int_a^b \alpha \mathrm{twobp}(x;t,h,+) dx - \int_a^b \alpha \mathrm{twobp}(x;t,h,-) dx \right| \\ & = \int_a^b \alpha \mathrm{bump}(x;t,h) dx \\ & = \frac{15\alpha [\mathfrak{C}(h)-1]h^4}{16} \\ & = \frac{[\mathfrak{C}(h)-1]h^4 \operatorname{Var}(\alpha \mathrm{bump}'''(\cdot;a,\mathfrak{h}))}{16} \end{split}$$

Substituting h in terms of n:

$$4n + 5 = \frac{b - a - 5\mathfrak{h}}{h} \ge (b - a - 5\mathfrak{h}) \left[ \frac{[\mathfrak{C}(h) - 1] \operatorname{Var}(\alpha \mathsf{bump'''}(\cdot; a, \mathfrak{h})))}{16\varepsilon} \right]^{1/4},$$
$$\ge \frac{b - a - 5\mathfrak{h}}{2} \left[ \frac{[\mathfrak{C}(0) - 1] \operatorname{Var}(\alpha \mathsf{bump'''}(\cdot; a, \mathfrak{h}))}{\varepsilon} \right]^{1/4}.$$

Since  $\alpha$  is an arbitrary positive number, the value of  $Var(\alpha bump'''(\cdot; a, \mathfrak{h}))$  is arbitrary.

Finally, comparing the upper bound on the computational cost of integral in (5.2) with the lower bound on the computational cost of the best algorithm in (6.3), both of them increase as  $\mathcal{O}((\operatorname{Var}(f''')/\varepsilon))^{1/4}$  as  $(\operatorname{Var}(f''')/\varepsilon)^{1/4} \to \infty$ . Thus integral is optimal.

#### NUMERICAL EXPERIMENTS

7.1 Traezoidale rule Consider the family of bump test functions defined by

$$f(x) = \begin{cases} b[4a^2 + (x-z)^2 + (x-z-a)|x-z-a| \\ -(x-z+a)|x-z+a|], & z-2a \le x \le z+2a, \quad (7.1) \\ 0, & \text{otherwise.} \end{cases}$$

with  $\log_{10}(a) \sim \mathcal{U}[-4, -1]$ ,  $z \sim \mathcal{U}[2a, 1 - 2a]$ , and  $b = 1/(4a^3)$  chosen to make  $\int_0^1 f(x) dx = 1$ . It follows that  $||f' - f(1) + f(0)||_1 = 1/a$  and  $Var(f') = 2/a^2$ . The probability that  $f \in \mathcal{C}_\tau$  is min  $(1, \max(0, (\log_{10}(\tau/2) - 1)/3))$ .

As an experiment, we chose 10000 random test functions and applied Algorithm 1 with an error tolerance of  $\varepsilon = 10^{-8}$  and initial  $\tau$  values of 10, 100, 1000. The algorithm is considered successful for a particular f if the exact and approximate integrals agree to within  $\varepsilon$ . The success and failure rates are given in Table 7.1. Our algorithm imposes a cost budget of  $N_{\text{max}} = 10^7$ . If the proposed  $n_{i+1}$  in Stages 2 or 3 exceeds  $N_{\text{max}}$ , then our algorithm returns a warning and falls back to the largest possible  $n_{i+1}$  not exceeding  $N_{\text{max}}$  for which  $n_{i+1} - 1$  is a multiple of  $n_i - 1$ . The probability that f initially lies in  $\mathcal{C}_{\tau}$  is the smaller number in the third column of Table 7.1, while the larger number is the empirical probability that f eventually lies in  $\mathcal{C}_{\tau}$  after possible increases in  $\tau$  made by Stage 2 of Algorithm 1. For this experiment Algorithm 1 was successful for all f that finally lie inside  $\mathcal{C}_{\tau}$  and for which no attempt was made to exceed the cost budget.

Some commonly available numerical algorithms in MATLAB are quad and integral [?] and the MATLAB Chebfun toolbox [?]. We applied these three routines

			Success	Success	Failure
	au	$\operatorname{Prob}(f \in \mathcal{C}_{\tau})$	No Warning	Warning	No Warning
Algorithm 1	10	$0\% \rightarrow 25\%$	25%	< 1%	75%
	100	$23\% \rightarrow 58\%$	56%	2%	42%
	1000	$57\% \rightarrow 88\%$	68%	20%	12%
quad			8%		92%
integral			19%		81%
chebfun			29%		71%

Table 7.1. The probability of the test function lying in the cone for the original and eventual values of  $\tau$  and the empirical success rate of Algorithm 1 plus the success rates of other common quadrature algorithms.

to the random family of test functions. Their success and failure rates are also recorded in Table 7.1. They do not give warnings of possible failure.

**7.2** Simpson's Rule I need to use a good example to run the tests. Then I will need to compare the results for both algorithms with other algorithms. After that, I need to compare trap and sim to get the conclusion such as sim has faster convergence rate than trap. This will require an sample function good to both trap and sim.
